Received January 26, 1998

The high-resolution spectrum of water vapor between 13 200 and 16 500 cm<sup>-1</sup> recorded by J.-Y. Mandin, J-P. Chevillard, C. Camy-Peyret, J.-M. Flaud, and J. W. Brault (1986. *J. Molec. Spectrosc.*, **116**, 167) is analyzed using high-accuracy linelists obtained using ab initio calculations and spectroscopically determined potential. Assignments to  $H_2^{16}O$  transitions are presented for 663 of the 795 unassigned lines presented in the original paper. In addition, 38 lines are reassigned. The majority of these assignments and reassignments are confirmed by combination differences. These assignments significantly extend the measured data for the  $4\nu$  and  $4\nu + \delta$  polyads and provide the first information on the (240), (033), (160), (170), and (071) bands. It is likely that a significant fraction of the remaining unassigned lines belong to  $H_2^{18}O$ . © 1998 Academic Press

## INTRODUCTION

Water is the major absorber of solar radiation in the earth's atmosphere. Yet at wavelengths covering the near infrared, visible, and ultraviolet, the spectrum of water remains poorly understood. In part this is because of the weakness of the water absorptions at these wavelengths, but spectra of water are also notoriously difficult to analyze. In particular, the most detailed observed water spectra in these regions (1, 2) contain many unassigned lines.

In this work we analyze the high-resolution water vapor spectrum of Mandin *et al.* (2). This spectrum was recorded using a Fourier transform spectrometer at the National Solar Observatory (Kitt Peak, Arizona) in the range 13 200–16 500 cm<sup>-1</sup>. The spectrum contained 2796 transitions. Mandin *et al.* were able to assign 1927 of these to 17  ${\rm H_2}^{16}{\rm O}$  vibrational bands belonging to the  $4\nu$  and  $4\nu + \delta$  polyads in their original work. A further 51 transitions were ascribed to  ${\rm H_2}^{18}{\rm O}$ ; 769 lines remained unassigned.

Recently we have pioneered methods of analyzing spectra of hot water recorded both in the laboratory (3-6) and sunspots (5-7). In the present work we employ these methods to assign the majority of the unassigned lines in the spectrum of Mandin *et al.* 

## **METHOD**

Analysis was performed using two linelists, ZVPT (6) and PS (8). These linelists have both been generated using high-accuracy variational calculations for the vibration—rotation motion of the water. The major difference between the linelists is that ZVPT is based on ab initio calculations

with explicit allowance made for non-Born-Oppenheimer effects (9), while the PS linelist used a potential that had been refined using spectroscopic data. Along with the two theoretical linelists, we also maintained a linelist generated using "trivial" transitions. Trivial transitions are ones that can be predicted accurately from known experimental energy levels. We started this linelist from Mandin *et al.*'s energy levels and PS's transition intensities. The linelist was continuously updated as new assignments were made using the calculated linelists.

Comparisons of the two theoretical linelists have been performed as part of our work on sunspot spectra (6, 7). The PS linelist is more accurate at estimating the frequency of individual transitions, particularly those with low J that concern us here. However the errors given by the PS linelist are often rather erratic. Conversely the ZVPT linelist is notable for giving very systematic errors, which allows one to make accurate predictions of the position of the next transition in a particular sequence or branch. The PS, but not the ZVPT, linelist contains a complete set of vibrational and rotational labels for each energy level and hence each transition. These are useful but must be treated with caution as the labels become increasing unreliable with excitation (7). For the upper states considered here about one-third of the labels proved to be incorrect. This problem appears to be particularly associated with representation of the normal mode-local mode behavior of  $4\nu$  and  $4\nu + \delta$  water polyads. Thus most levels associated with (103) are labeled by PS as belonging to (301); similarly (122) levels are usually given as (320), and those with belonging to (113) as (311).

The spectrum of Mandin *et al.* (2) contains a considerable range of intensities. The strongest transitions show 100% peak absorption under the experimental conditions used, while there are many weak transitions with peak absorption of 0.5% or less. Mandin *et al.* assigned nearly all the strong

transitions. The strongest unassigned line has a peak absorption of 23%, meaning that there was still a factor of 50 between the strongest and weakest unassigned lines.

The first step in our assignments therefore was to generate 300-K absorption spectra in the range 13 200–16 500 cm<sup>-1</sup>, using both ZVPT and PS linelists. These were then compared with the experimental spectra starting from the strongest transitions. Tentative assignments were made by comparison with the computed linelists and then confirmed by looking for a further transition associated with the same upper state. Transitions confirmed by these combination differences gave new energy levels that were then used to look for further trivial assignments.

# RESULTS AND DISCUSSION

Table 1 presents our newly assigned lines in the 13 200–16 500-cm<sup>-1</sup> region. Frequencies for these transitions have been taken electronically from the HITRAN database (10). Intensities are those measured by Mandin *et al.* (2) and are in units of tenth of a percent of peak absorption. A full list of transitions, both unassigned and assigned by them, is given by Mandin *et al.* 

Table 1 contains 701 newly assigned lines. The majority of these lines, 487, have, as indicated, been confirmed by combination differences. These assignments can be therefore be regarded as secure. The remaining 214 line assignments were obtained only from direct comparison with the linelists. While we believe these assignments to be correct, they must naturally be regarded with more caution.

Our assigned transitions come from 22 different vibrational bands of  $\mathrm{H_2}^{16}\mathrm{O}$ , five of which have not been previously observed. Table 2 summarizes the data obtained for each vibrational band; the results of Mandin *et al.* are also summarized. We have not systematically rechecked all Mandin *et al.*'s assignments, however we found 38 lines that had to be reassigned on the grounds of combination differences and other considerations. These lines are also given in Table 1 and the summary of Mandin *et al.*'s data in Table 2 has been adjusted to allow for them. We found three weak lines, which are given in Table 1, were incorrectly assigned by Mandin *et al.* but have so far defied our attempts to reassign them.

Looking at our new vibrational bands we determine the (240) and (033) are weaker bands arising from the  $4\nu$  and  $4\nu + \delta$  polyads, respectively, and are the sort of band one

298 POLYANSKY ET AL.

*Note.* For each band the number of line assignments made and energy levels determined are given for both the previous and this work. The number of misassigned lines, "mis," found in the work of Mandin *et al.* is also given.

- <sup>a</sup> Estimated vibrational term value (see text).
- <sup>b</sup> Assignments confirmed by combination differences.
- <sup>c</sup> Assignments made only by comparisons with calculated linelists.
- <sup>d</sup> Term values for these states given in Table 3.

would expect to be responsible for weak transitions at near infrared wavelengths. Conversely, although (170) and (071) belong formally to the  $4\nu + \delta$  polyad, one would have anticipated that transitions to states with seven quanta of bend would be too weak to be observed at the sensitivity of the Kitt Peak spectra. However, it transpires that the transitions we assign to these states, all but two of which have been confirmed by combination differences, are isolated ones that steal intensity from nearby "bright" states. Such interactions are included automatically in the variational calculations used to construct the linelists used here. As these interactions are localized we would not expect to find further transitions involving these vibrational bands. One level at 14 349.776 cm<sup>-1</sup> was found to be involved in four distinct transitions. By comparison with the PS linelist, this level was tentatively assigned as  $(160)7_{52}$ .

Also given in Table 2 are vibrational term values ("band origins") for 21 of the vibrational bands for which we make assignments. For 14 of these bands, transitions have been

assigned that involve the  $0_{00}$  state of vibrational state concerned. In these cases it is possible to quote observed band origins. In particular we find the previously unobserved (071) and (033) band origins at 13 835.72 and 15 534.71 cm<sup>-1</sup>, respectively. For the other seven vibrational states no transitions involving the  $0_{00}$  state have been assigned. In these cases the band origin cannot be determined directly from the observed data, but it is possible to estimate the band origin using the values given by the PS linelist corrected for the systematic errors relative for observed rotationally excited members of the band. This method of obtaining band origins should be accurate to about  $\pm 0.1 \text{ cm}^{-1}$ . For (240), (042), and (170) these results represent the first experimental estimates of the band origin. For the (320) state, reassignments, confirmed by combination differences, lead us to the conclusion that the band origin lies 1.4 cm<sup>-1</sup> lower than the value quoted in Table 1 of Mandin et al. (2). Estimated band origins for the (141), (004), and (330) states are given by Rothman et al. (10). Our improved values are consistent with theirs for (141) but are 1 cm<sup>-1</sup> higher for the (004) and (330) states.

Table 3 presents water energy levels obtained from our and Mandin et al.'s data. Results are presented only for vibrational states for which there is a significant amount of new data. Included in this tabulation are results for the (071) vibrational states. Recently, we assigned a number of transitions to the (061) - (050) and (071) - (060) systems in sunspot spectra of hot water (7). Since there was no previous data on the (050), (060), (061), or (071) vibrational states, we were unable to extract energy levels for these states from our assignments. The new assignments to the (071) vibrational bands in principle give us a handle on this problem. So far there are insufficient assigned transitions to build a reliable set of energy levels for the vibrational states. However, we are undertaking further work on hot water spectra both in the  $(v_1, v_2 + 1, v_3 + 1) - (v_1, v_2, v_3)$  region and the region dominated by bending transitions of the sort (0,  $v_2 + 1,0 - (0, v_2, 0)$ , see (3). In particular, hotter laboratory spectra should hopefully be sensitive to bands involving (060). These studies should lead to the elucidation of the energy levels of these and other states containing significant bending excitation.

Although we have assignments for nearly all the unassigned transitions of Mandin *et al.*, 132 lines remain unassigned. All these transitions are weak. Although we are confident that, particularly with further experimental input, we will in due course assign all the  $H_2^{16}O$  transitions in this spectrum, it must be remembered that transitions belonging to  $H_2^{18}O$  are also present in the spectrum. It is likely that about a half of our unassigned transitions actually involve  $H_2^{18}O$ . Of course  $H_2^{18}O$  spectra can also be analyzed using the linelist techniques employed here, but as yet we do not have the equivalent linelists for this system. We intend to address this problem in future work.

### CONCLUSIONS

A significant fraction of the high-resolution near infrared water vapor spectrum of Mandin *et al.* (2) has remained unassigned in the literature for over a decade. By use of linelists based on high-accuracy variational calculations, we have successfully assigned over 80% of the unassigned lines in this spectrum. This has led to the first information on five vibrational states and values of the vibrational band origin for four other states. This demonstrates that the technique of assignments based on variational calculations, which we had successfully applied to the spectra of hot water at a number of longer wavelengths (3-7), is equally applicable to short wavelength spectra of room temperature water.
